# **SECTION 8: ARRAYS**

# ARRAYS

Keeping a Group of Variables

An “int” array of size 12:

The index number

x[0]	x[1]	x[2]	x[3]	x[4]	x[5]	x[6]	x[7]	x[8]	x[9]	x[10]	x[11]
6	8	45	233	-4	0	4	67	31	3456	34	-69

1<sup>st</sup> element

**NOTE:** The first element of each array is **ALWAYS** called the 0<sup>th</sup> element.

**NOTE:** The indices can only be  $\geq 0$

# ARRAYS

## Declaration of Arrays

Declaring an Integer Array of size 12:

```
int arrayName[12];
```

“**Arrays**” are **objects** (non-primitive types) that occupy space in memory.

**NOTE:** The **LAST** element in an array of size “n” is the element with index “n-1”

# ARRAYS

## Use of Arrays

After declaring the array, we can use each element of an array like a variable:

```
arrayName[3] = 2;  
arrayName[4] = arrayName [3] * 5;  
arrayName[5]++;
```

**Example:**

Write a program that reads an integer N, then reads that many integers and calculate the average of these numbers.

We can also initialize arrays like other primitive data types.

```
int n[] = {10, 40, 3, -2, 99};
```

# ARRAYS

## Example

We can get the **LENGTH** of an array by using the `sizeof()` function.

```
int d[23];  
int size = sizeof(d)/sizeof(d[0]);  
std::cout << "The length of array d is " << size);
```

### Example:

Write a program that reads an integer N, and then reads N integer elements from the user. You want to check whether this sequence of numbers is symmetric or not. (i.e., 1 2 3 4 5 5 4 3 2 1 is symmetric, 1 2 3 4 5 6 4 3 2 1 is NOT symmetric)

# ENHANCED FOR STATEMENT

```
int size = sizeof(array)/sizeof(array[0]);  
  
for (int counter=0; counter< size; counter++){  
    int element = array[counter];  
    total += element;  
}
```

=

```
for (int element:array){  
    total += element;  
}
```

**Example:**

Write a program that reads a sequence of characters. You want to count the lowercase and the uppercase letters in this sequence. The sequence is finished when % is entered. You should ignore all other characters.

# PASSING ARRAYS TO FUNCTIONS

Like any other primitive data types, you can pass arrays to a function.

```
int function_ex(int an_integer, int integer_array[], double double_array[])
```

**Example:**

Write a program that takes two int values rankA and rankB, then reads the coefficients of two polynomials from the user. The first polynomial has rankA+1 many coefficients, and the second polynomial has rankB+1 many coefficients.

Define a function (addPolynom) that performs the addition operation on these polynomials.

**NOTE:** Unlike other data types, a function **CANNOT** return an array.

# ARRAYS

## Example

**Example:**

Write a program that takes two int values rankA and rankB, then reads the coefficients of two polynomials from the user. The first polynomial has rankA+1 many coefficients, and the second polynomial has rankB+1 many coefficients.

Define a function (multPolynom) that performs the multiplication operation on these polynomials.

# SIZE OF AN ARRAY

How to increase the size of an array?

x[0]	x[1]	x[2]	x[3]	x[4]	x[5]	x[6]	x[7]	x[8]	x[9]	x[10]	x[11]
6	8	45	233	-4	0	4	67	31	3456	34	-69

x[0]	x[1]	x[2]	x[3]	x[4]	x[5]	x[6]	x[7]	x[8]	x[9]	x[10]	x[11]	x[12]	x[13]
6	8	45	233	-4	0	4	67	31	3456	34	-69	!?	?!

**NOTE:** Sizes of arrays CANNOT be changed during the program.
